Package 'AIMS'

July 18, 2025

Type Package

Title AIMS : Absolute Assignment of Breast Cancer Intrinsic Molecular
Subtype

Version 1.41.0

Date 2014-06-25

Description This package contains the AIMS
implementation. It contains necessary functions to assign the
five intrinsic molecular subtypes (Luminal A, Luminal B,
Her2-enriched, Basal-like, Normal-like). Assignments could be
done on individual samples as well as on dataset of gene
expression data.

AIMSmodel   *The AIMS model*

Description

This is the model definition for AIMS. It contains the naive bayes classifier composed of the 100 rules described in Paquet et al. "Absolute assignment of breast cancer intrinsic molecular subtype" (under review at JNCI).

Usage

```
AIMSmodel
```

Details

This is the AIMS model define using 100 simple rules of the form gene A < gene B and combine within a naive bayes classifier within e1071. (Paquet et al. under review JNCI)

Briefly, using a suitably large training dataset(~5000 gene breast cancer gene expression profiles), the approach identifies a small set of simple binary rules (~20) that examine the raw expression measurements for pairs of genes from a single breast cancer patient, and only that patient. The binary rules are of the form "if the expression of gene x is greater than gene y, then tend to assign subtype z for that patient". Subtypes could be : Basal, Her2, LumA, LumB, or Normal. The collection of binary rules is combined for a single estimation of a patient subtype via a single probabilistic model using naiveBayes in e1071. In this way, since only expression levels of genes with a single patient is considered, the method represents a promising approach to ablate the instability caused by relativistic approaches (Paquet et al. in review at JNCI).

Value

all.pairs   The 100 rules in AIMS in the form EntrezID gene A < EntrezID gene B

k   The selected number of optimal rules. For AIMS we have shown it is 20.

one.vs.all.tsp   The Naive bayes classifier used in combination with the 100 rules

selected.pairs.list
                 The list of rules sorted from the best discriminating rule to the least discriminating rules subdivided by subtype.

applyAIMS | *Function that will assign the AIMS subtype to a gene expression matrix*

Description

Given a gene expression matrix D where rows correspond to genes and columns to samples and a list of Entrez gene ids, this function will assign the breast cancer molecular subtype using Absolute PAM50 (AIMS) (Paquet et al. under review at JNCI).

Usage

```
applyAIMS (eset, EntrezID)
```

Arguments

eset
: An ExpressionSet (Biobase) or a matrix D of gene expression. Rows are genes and columns are samples (tumor from breast cancer patients).

EntrezID
: A character vector corresponding to the Entrez Ids of the genes of matrix D.

Details

We defined Absolute assignment of breast cancer Molecular Intrinsic Subtypes (AIMS) to stabilize the actual PAM50. The idea of the approach is to use simple rules of the form "if gene A expression < gene B expression assigned sample to subtype X". By using those simple rules we are able to assign subtype using only the expression values of one patient. We have shown AIMS recapitulates PAM50 subtype assignments and preserved the prognostic values of the subtypes. This function will return the subtype assignment as well as the posterior probabilities for all the subtypes.

Value

cl
: Subtypes identified by the AIMS. It could be either "Basal", "Her2", "LumA", "LumB" or "Normal".

prob
: A vector corresponding to the posterior probabilities of the subtypes in cl.

all.probs
: A matrix of all the posterior probabilities for all the samples and all the subtypes

rules.matrix
: The matrix of 100 rules used by AIMS to assign the breast cancer subtypes. Rows correspond to rules and columns to samples. This is a 0,1 matrix in which 1 represents the rules is true and 0 the rule is false

data.used
: The expression values used to evaluate the simple rules.

EntrezID.used
: The list of Entrez ids used by AIMS

   message("Identical assignment batch and random 50")
}else{
   message("Different assignment batch and random 50")
}
```

| mcgillExample | *Sample of a breast cancer gene expression dataset generated at McGill University* |

Description

This is a breast cancer gene expression dataset generated at McGill University using the Affymetrix Gene ST platform. This is the validation dataset used in AIMS' paper and in use in the examples of AIMS.

Usage

```
mcgillExample
```

Details

A sample of a breast cancer gene expression dataset currently generated at McGill University on the Affymetrix gene ST platform.

Value

D	A matrix of gene gene expression, rows are genes and columns are samples
EntrezID	A vector of Entrez ids corresponding to genes (rows) of D
