# Package 'optedr' 

November 18, 2022
Title Calculating Optimal and D-Augmented Designs
Version 2.0.0
Description Calculates D-, Ds-, A- and I-optimal designs for non-linear models, via an implementation of the cocktail algorithm (Yu, 2011, [doi:10.1007/s11222-010-9183-2](doi:10.1007/s11222-010-9183-2)). Compares designs via their efficiency, and D-augments any design with a controlled efficiency. An efficient rounding function has been provided to transform approximate designs to exact designs.

add_design Add two designs

## Description

Add two designs

## Usage

add_design(design_1, design_2, alpha)

## Arguments

| design_1 | A dataframe with 'Point' and 'Weight' as columns that represent the first design <br> to add |
| :--- | :--- |
| design_2 | A dataframe with 'Point' and 'Weight' as columns that represent the second <br> design to add |
| alpha | Weight of the first design |

## Value

A design as a dataframe with the weighted addition of the two designs

$$
\text { add_points } \quad \text { Update design given crosspoints and alpha }
$$

## Description

Given a set of points, a weight and the design, the function adds these points to the new design with uniform weight, and combined weight alpha

## Usage

add_points(points, alpha, design)

## Arguments

| points | Points to be added to the design |
| :--- | :--- |
| alpha | Combined weight of the new points to be added to the design |
| design | A design as a dataframe with "Point" and "Weight" columns |

## Value

A design as a dataframe with "Point" and "Weight" columns that is the addition of the design and the new points

```
augment_design Augment Design
```

## Description

Augments a design. The user gives an initial design for which he would like to add points and specifies the weight of the new points. Then he is prompted to choose a minimum efficiency. After that, the candidate points region is calculated and the user can choose the points and weights to add.

## Usage

augment_design(
criterion,
init_design,
alpha,
model,
parameters,
par_values,
design_space,
calc_optimal_design,
par_int = NA,
matB = NA,
distribution = NA,
weight_fun $=$ function(x) 1
)

## Arguments

criterion character variable with the chosen optimality criterion. Can be one of the following:

- 'D-Optimality'
- 'Ds-Optimality'
- 'A-Optimality'
- 'I-Optimality'

```
init_design dataframe with "Point" and "Weight" columns that represents the initial design
                    to augment
alpha combined weight of the new points
model formula that represents the model with }\textrm{x}\mathrm{ as the independent variable
parameters character vector with the unknown parameters of the model to estimate
par_values numeric vector with the initial values of the unknown parameters
design_space numeric vector with the limits of the space of the design
calc_optimal_design
    boolean parameter, if TRUE, the optimal design is calculated and efficiencies of
    the initial and augmented design are given
par_int optional numeric vector with the index of the parameters of interest for Ds-
    optimality.
matB optional matrix of dimensions k x k, integral of the information matrix of the
    model over the interest region for I-optimality.
distribution character specifying the probability distribution of the response. Can be one of
        the following:
- 'Homoscedasticity'
- 'Gamma', which can be used for exponential or normal heteroscedastic with constant relative error
- 'Poisson'
- 'Logistic'
- 'Log-Normal' (work in progress)
weight_fun optional one variable function that represents the square of the structure of variance, in case of heteroscedastic variance of the response
```

## Value

A dataframe that represents the D-augmented design

## Examples

```
init_des <- data.frame("Point" = c(30, 60, 90), "Weight" = c(1/3, 1/3, 1/3))
augment_design("D-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a","b","c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), TRUE)
augment_design("D-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a","b","c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), FALSE)
```

```
check_inputs Check Inputs
```

## Description

Function to check that the inputs given to the function opt_des are correct. If not, throws the correspondent error message.

## Usage

```
    check_inputs(
        Criterion,
        model,
        parameters,
        par_values,
        design_space,
        init_design,
        join_thresh,
        delete_thresh,
        delta,
        tol,
        tol2,
        par_int,
        matB,
        reg_int,
        desired_output,
        weight_fun
    )
```

## Arguments

Criterion character variable with the chosen optimality criterion. Can be one of the following:

- 'D-Optimality'
- 'Ds-Optimality'
- 'A-Optimality'
- 'I-Optimality'
model formula describing the model to calculate the optimal design. Must use x as the variable.
parameters character vector with the parameters of the models, as written in the formula.
par_values numeric vector with the parameters nominal values, in the same order as given in parameters.
design_space numeric vector with the limits of the space of the design.
init_design optional dataframe with the initial design for the algorithm. A dataframe with two columns:
- Point contains the support points of the design.
- Weight contains the corresponding weights of the Points.
join_thresh optional numeric value that states how close, in real units, two points must be in order to be joined together by the join heuristic.
delete_thresh optional numeric value with the minimum weight, over 1 total, that a point needs to have in order to not be deleted from the design.
delta optional numeric value in $(0,1)$, parameter of the algorithm.
tol optional numeric value for the convergence of the weight optimizing algorithm.
tol2 optional numeric value for the stop criterion: difference between maximum of sensitivity function and optimality criterion.
par_int optional numeric vector with the index of the parameters of interest for Dsoptimality.
matB optional matrix of dimensions $\mathrm{kx} \mathrm{k}^{\text {, integral of the information matrix of the }}$ model over the interest region for I-optimality.
reg_int optional numeric vector of two components with the bounds of the interest region for I-Optimality.
desired_output not functional yet: decide which kind of output you want.
weight_fun optional one variable function that represents the square of the structure of variance, in case of heteroscedastic variance of the response

```
crit
Master function for the criterion function
```

## Description

Depending on the Criterion input, the function returns the output of the corresponding criterion function given the information matrix.

## Usage

crit(Criterion, $M, k=0$, par_int $=c(1)$, matB $=N A)$

## Arguments

Criterion character variable with the chosen optimality criterion. Can be one of the following:

- 'D-Optimality'
- 'Ds-Optimality'
- 'A-Optimality'
- 'I-Optimality'

M
information matrix for which the criterion value wants to be calculated.
$\mathrm{k} \quad$ numeric variable with the number of parameters of the model. Taken from the number of rows of the matrix if omitted.

```
par_int numeric vector with the index of the parameters of interest of the model. Only
    for "Ds-Optimality".
matB matrix of the integral of the information matrix over the interest region. Only
    for "I-Optimality".
```

## Value

Numeric value of the optimality criterion for the information matrix.
crosspoints Calculate crosspoints

## Description

Given the parameters for augmenting a design, this function calculates the crosspoints in the efficiency function that delimit the candidate points region

## Usage

crosspoints(val, sens, gridlength, tol, xmin, xmax)

## Arguments

| val | Efficiency value to solve in the curve relationing the space of the design and <br> efficiency of new design |
| :--- | :--- |
| sens | Sensitivity function of the design for the model |
| gridlength | Number of points in the grid to find the crosspoints |
| tol | Tolerance that establishes how close two points close to one another are consid- <br> ered the same |
| xmin | Minimum of the space of the design |
| $x m a x$ | Maximum of the space of the design |

## Value

A numeric vector of crosspoints that define the candidate points region

## Description

D-Augments a design. The user gives an initial design for which he would like to add points and specifies the weight of the new points. Then he is prompted to choose a minimum efficiency. After that, the candidate points region is calculated and the user can choose the points and weights to add.

## Usage

```
daugment_design(
        init_design,
        alpha,
        model,
        parameters,
        par_values,
        design_space,
        calc_optimal_design,
        weight_fun = function(x) 1
    )
```

## Arguments

| init_design | dataframe with "Point" and "Weight" columns that represents the initial design <br> to augment |
| :--- | :--- |
| alpha | combined weight of the new points <br> formula that represents the model with $x$ as the independent variable |
| model | parameters |
| character vector with the unknown parameters of the model to estimate |  |

## Value

A dataframe that represents the D -augmented design

## See Also

Other augment designs: dsaugment_design(), laugment_design()

## Examples

```
init_des <- data.frame("Point" = c(30, 60, 90), "Weight" = c(1/3, 1/3, 1/3))
augment_design("D-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a","b", "c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), TRUE)
augment_design("D-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a","b","c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), FALSE)
```

dcrit
Criterion function for D-Optimality

## Description

Calculates the value of the D-Optimality criterion function, which follows the expression:

$$
\phi_{D}=\left(\frac{1}{|M|}\right)^{1 / k}
$$

## Usage

$\operatorname{dcrit}(M, k)$

## Arguments

M information matrix for which the criterion value wants to be calculated.
$\mathrm{k} \quad$ numeric variable with the number of parameters of the model. Taken from the number of rows of the matrix if omitted.

## Value

numeric value of the D-optimality criterion for the information matrix.

```
delete_points Remove low weight points
```

## Description

Removes the points of a design with a weight lower than a threshold, delta, and distributes that weights proportionally to the rest of the points.

## Usage

delete_points(design, delta)

## Arguments

design The design from which to remove points as a dataframe with two columns:

- Point contains the support points of the design.
- Weight contains the corresponding weights of the Points.
delta The threshold from which the points with such a weight or lower will be removed.

## Value

The design without the removed points.
design_efficiency Efficiency between optimal design and a user given design

## Description

Takes an optimal design provided from the function opt_des and a user given design and compares their efficiency

## Usage

design_efficiency(opt_des_obj, design)

## Arguments

opt_des_obj an object given by the function opt_des.
design dataframe that represents the design. Must have two columns:

- Point contains the support points of the design.
- Weight contains the corresponding weights of the Points.

## Value

The efficiency as a value between 0 and 1

## See Also

opt_des

## Examples

```
result <- opt_des("D-Optimality", y ~ a * exp(-b / x), c("a", "b"), c(1, 1500), c(212, 422))
design <- data.frame("Point" = c(220, 240, 400), "Weight" = c(1 / 3, 1 / 3, 1 / 3))
design_efficiency(result, design)
```

dsaugment_design Ds-Augment Design

## Description

Ds-Augments a design. The user gives an initial design for which he would like to add points and specifies the weight of the new points. Then he is prompted to choose a minimum efficiency. After that, the candidate points region is calculated and the user can choose the points and weights to add.

## Usage

dsaugment_design(
init_design, alpha, model, parameters, par_values, par_int, design_space, calc_optimal_design, weight_fun $=$ function(x) 1
)

## Arguments

| init_design | dataframe with "Point" and "Weight" columns that represents the initial design <br> to augment |
| :--- | :--- |
| alpha | combined weight of the new points <br> formula that represents the model with $x$ as the independent variable |
| model |  |
| parameters | character vector with the unknown parameters of the model to estimate <br> par_values <br> numeric vector with the initial values of the unknown parameters |
| par_int | optional numeric vector with the index of the parameters of interest for Ds- <br> optimality. |
| design_space | numeric vector with the limits of the space of the design |
| calc_optimal_design |  |
| boolean parameter, if TRUE, the optimal design is calculated and efficiencies of |  |
| the initial and augmented design are given |  |

## Value

A dataframe that represents the Ds-augmented design

## See Also

Other augment designs: daugment_design(), laugment_design()

## Examples

```
init_des <- data.frame("Point" = c(30, 60, 90), "Weight" = c(1/3, 1/3, 1/3))
augment_design("Ds-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a","b","c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), par_int = c(1), TRUE)
augment_design("Ds-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a","b","c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), par_int = c(1), FALSE)
```

    dscrit Criterion function for Ds-Optimality
    
## Description

Calculates the value of the Ds-Optimality criterion function, which follows the expression:

$$
\phi_{D s}=\left(\frac{\left|M_{22}\right|}{|M|}\right)^{1 / s}
$$

## Usage

dscrit(M, par_int)

## Arguments

M information matrix for which the criterion value wants to be calculated.
par_int numeric vector with the index of the parameters of interest of the model.

## Value

Numeric value of the Ds-optimality criterion for the information matrix.
dsens Sensitivity function for D-Optimality

## Description

Calculates the sensitivity function from the gradient vector and the Identity Matrix.

## Usage

dsens(grad, M)

## Arguments

grad A function in a single variable that returns the partial derivatives vector of the model.

M Information Matrix for the sensitivity function.

## Value

The sensitivity function as a matrix of single variable.
dssens Sensitivity function for Ds-Optimality

## Description

Calculates the sensitivity function from the gradient vector, the Identity Matrix and the parameters of interest.

## Usage

dssens(grad, M, par_int)

## Arguments

grad

M
par_int Numeric vector of the indexes of the parameters of interest for Ds-Optimality.

## Value

The sensitivity function as a matrix of single variable.

## Description

Function that calculates the Ds-Optimal designs for the interest parameters given by intPar. The rest of the parameters can help the convergence of the algorithm.

## Usage

```
DsWFMult(
    init_design,
    grad,
    par_int,
    min,
    max,
    grid.length,
    join_thresh,
    delete_thresh,
    delta_weights,
    tol,
    tol2
    )
```

## Arguments

init_design optional dataframe with the initial design for the algorithm. A dataframe with two columns:

- Point contains the support points of the design.
- Weight contains the corresponding weights of the Points.
grad function of partial derivatives of the model.
par_int numeric vector with the index of the parameters of interest. Only necessary when the Criterion chosen is 'Ds-Optimality'.
$\min \quad$ numeric value with the inferior bound of the space of the design.
$\max \quad$ numeric value with the upper bound of the space of the design.
grid.length numeric value that gives the grid to evaluate the sensitivity function when looking for a maximum.
join_thresh numeric value that states how close, in real units, two points must be in order to be joined together by the join heuristic.
delete_thresh numeric value with the minimum weight, over 1 total, that a point needs to have in order to not be deleted from the design.
delta_weights numeric value in $(0,1)$, parameter of the algorithm.
tol numeric value for the convergence of the weight optimizing algorithm.
tol2 numeric value for the stop condition of the algorithm.

## Value

list correspondent to the output of the correspondent algorithm called, dependent on the criterion. A list of two objects:

- optdes: a dataframe with the optimal design in two columns, Point and Weight.
- sens: a plot with the sensitivity function to check for optimality of the design.

## See Also

Other cocktail algorithms: DWFMult(), IWFMult(), WFMult ()

## Description

Function that calculates the DsOptimal design. The rest of the parameters can help the convergence of the algorithm.

```
Usage
    DWFMult(
        init_design,
        grad,
        min,
        max,
        grid.length,
        join_thresh,
        delete_thresh,
        k,
        delta_weights,
        tol,
        tol2
    )
```

## Arguments

init_design optional dataframe with the initial design for the algorithm. A dataframe with two columns:

- Point contains the support points of the design.
- Weight contains the corresponding weights of the Points.
grad function of partial derivatives of the model.
min numeric value with the inferior bound of the space of the design.
$\max \quad$ numeric value with the upper bound of the space of the design.
grid.length numeric value that gives the grid to evaluate the sensitivity function when looking for a maximum.
join_thresh numeric value that states how close, in real units, two points must be in order to be joined together by the join heuristic.
delete_thresh numeric value with the minimum weight, over 1 total, that a point needs to have in order to not be deleted from the design.
$\mathrm{k} \quad$ number of unknown parameters of the model.
delta_weights numeric value in $(0,1)$, parameter of the algorithm.
tol numeric value for the convergence of the weight optimizing algorithm.
tol2 numeric value for the stop condition of the algorithm.

## Value

list correspondent to the output of the correspondent algorithm called, dependent on the criterion. A list of two objects:

- optdes: a dataframe with the optimal design in two columns, Point and Weight.
- sens: a plot with the sensitivity function to check for optimality of the design.

## See Also

Other cocktail algorithms: DsWFMult(), IWFMult(), WFMult()

## eff <br> Efficiency between two Information Matrices

## Description

Efficiency between two Information Matrices

## Usage

eff(Criterion, mat1, mat2, $k=0$, intPars $=c(1)$, matB $=N A)$

## Arguments

Criterion character variable with the chosen optimality criterion. Can be one of the following:

- 'D-Optimality'
- 'Ds-Optimality'
- 'A-Optimality'
- 'I-Optimality'
mat1 first information matrix, for the numerator.
mat2 second information matrix, for the denominator.
k
intPars numeric vector with the index of the parameters of interest of the model. Only for "Ds-Optimality".
matB matrix of the integral of the information matrix over the interest region. Only for "I-Optimality".

## Value

Efficiency of first design with respect to the second design, as a decimal number.

```
efficient_round Efficient Round
```

## Description

Takes an approximate design, and a number of points and converts the design to an approximate design. It uses the multiplier ( $n-1 / 2$ ) and evens the total number of observations afterwards.

## Usage

efficient_round(design, $n$, tol $=1 \mathrm{e}-05$ )

## Arguments

design a dataframe with columns "Point" and "Weight" that represents a design $\mathrm{n} \quad$ an integer that represents the desired number of observations of the exact design tol optional parameter for the consideration of an integer in the rounding process

## Value

a data.frame with columns "Point" and "Weight" representing an exact design with n observations

## Examples

```
design_test <- data.frame("Point" = seq(1, 5, length.out = 7),
            "Weight" = c(0.1, 0.0001, 0.2, 0.134, 0.073, 0.2111, 0.2818))
efficient_round(design_test, 20)
exact_design <- efficient_round(design_test, 21)
aprox_design <- exact_design
aprox_design$Weight <- aprox_design$Weight/sum(aprox_design$Weight)
```

## findmax Find Maximum

## Description

Searches the maximum of a function over a grid on a given interval.

## Usage

findmax(sens, min, max, grid.length)

## Arguments

| sens | A single variable numeric function to evaluate. |
| :--- | :--- |
| min | Minimum value of the search interval. |
| max | Maximum value of the search interval. |
| grid.length | Length of the search interval. |

## Value

The value at which the maximum is obtained
findmaxval Find Maximum Value

## Description

Searches the maximum of a function over a grid on a given interval.

## Usage

findmaxval(sens, min, max, grid.length)

## Arguments

| sens | A single variable numeric function to evaluate. |
| :--- | :--- |
| $\min$ | Minimum value of the search interval. |
| $\max$ | Maximum value of the search interval. |
| grid.length | Length of the search interval. |

## Value

The value of the maximum
findminval Find Minimum Value

## Description

Searches the maximum of a function over a grid on a given grid.

## Usage

findminval(sens, min, max, grid.length)

## Arguments

sens a single variable numeric function to evaluate.
min minimum value of the search grid.
$\max \quad$ maximum value of the search grid.
grid.length length of the search grid.

## Value

The value of the minimum
getCross2 Give effective limits to candidate points region

## Description

Given the start of the candidates points region, the parity of the crosspoints and the boundaries of the space of the design returns the effective limits of the candidate points region. Those points, taken in pairs from the first to the last delimit the region.

## Usage

getCross2(cross, min, max, start, par)

## Arguments

cross Vector of crosspoints in the sensitivity function given an efficiency and weight
min Minimum of the space of the design
$\max \quad$ Maximum of the space of the design
start Boolean that gives the effective start of the candidate points region
par Boolean with the parity of the region

## Value

Vector of effective limits of the candidate points region. Taken in pairs from the beginning delimit the region.
getPar Parity of the crosspoints

## Description

Determines if the number of crosspoints is even or odd given the vector of crosspoints

## Usage

getPar(cross)

## Arguments

cross Vector of crosspoints in the sensitivity function given an efficiency and weight

## Value

True if the number of crosspoints is even, false otherwise
getStart Find where the candidate points region starts

## Description

Given the crosspoints and the sensitivity function, this function finds where the candidate points region starts, either on the extreme of the space of the design or the first crosspoints

## Usage

getStart(cross, min, max, val, sens_opt)

## Arguments

| cross | Vector of crosspoints in the sensitivity function given an efficiency and weight |
| :--- | :--- |
| $\min$ | Minimum of the space of the design |
| $\max$ | Maximum of the space of the design |
| val | Value of the sensitivity function at the crosspoints |
| sens_opt | Sensitivity function |

## Value

True if the candidate points region starts on the minimum, False otherwise

```
get_augment_region Get Augment Regions
```

## Description

Given a model and criterion, calculates the candidate points region. The user gives an initial design for which he would like to add points and specifies the weight of the new points. Then he is prompted to choose a minimum efficiency. After that, the candidate points region is calculated.

## Usage

```
get_augment_region(
    criterion,
    init_design,
    alpha,
    model,
    parameters,
    par_values,
    design_space,
    calc_optimal_design,
    par_int = NA,
    matB = NA,
    distribution = NA,
    weight_fun = function(x) 1
)
```

## Arguments

criterion character with the chosen optimality criterion. Can be one of the following:

- 'D-Optimality'
- 'Ds-Optimality'
- 'A-Optimality'
- 'I-Optimality'
init_design dataframe with "Point" and "Weight" columns that represents the initial design to augment
alpha combined weight of the new points
model formula that represent the model with x as the independent variable
parameters character vector with the unknown parameters of the model to estimate
par_values numeric vector with the initial values of the unknown parameters
design_space numeric vector with the limits of the space of the design
calc_optimal_design
boolean parameter, if TRUE, the optimal design is calculated and efficiencies of the initial and augmented design are given

```
par_int optional numeric vector with the index of the parameters of interest for Ds-
    optimality.
matB optional matrix of dimensions k x k, integral of the information matrix of the
    model over the interest region for I-optimality.
distribution character specifying the probability distribution of the response. Can be one of
        the following:
    - 'Homoscedasticity'
    - 'Gamma', which can be used for exponential or normal heteroscedastic
    with constant relative error
    - 'Poisson'
    - 'Logistic'
    - 'Log-Normal' (work in progress)
weight_fun optional one variable function that represents the square of the structure of vari-
        ance, in case of heteroscedastic variance of the response
```

## Value

A vector of the points limiting the candidate points region

## Examples

```
init_des <- data.frame("Point" = c(30, 60, 90), "Weight" = c(1/3, 1/3, 1/3))
get_augment_region("D-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a","b","c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), TRUE)
get_augment_region("D-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a","b","c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), FALSE)
get_daugment_region Get \(D\)-augment region
```

## Description

Given a model, calculates the candidate points region for D-Optimality. The user gives an initial design for which he would like to add points and specifies the weight of the new points. Then he is prompted to choose a minimum efficiency. After that, the candidate points region is calculated.

```
Usage
    get_daugment_region(
    init_design,
    alpha,
    model,
    parameters,
    par_values,
    design_space,
    calc_optimal_design,
    weight_fun = function(x) 1
)
```

## Arguments

| init_design | dataframe with "Point" and "Weight" columns that represents the initial design <br> to augment <br> combined weight of the new points <br> formula that represent the model with $x$ as the independent variable <br> character vector with the unknown parameters of the model to estimate |
| :--- | :--- |
| alpha | model <br> parameters <br> par_values <br> nesign_space vector with the initial values of the unknown parameters <br> calc_optimal_design <br> numeric vector with the limits of the space of the design |
| boolean parameter, if TRUE, the optimal design is calculated and efficiencies of |  |
| the initial and augmented design are given |  |
| optional one variable function that represents the square of the structure of vari- |  |
| ance, in case of heteroscedastic variance of the response |  |

## Value

A vector of the points limiting the candidate points region

## Examples

```
init_des <- data.frame("Point" = c(30, 60, 90), "Weight" = c(1/3, 1/3, 1/3))
get_augment_region("D-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a","b", "c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), TRUE)
get_augment_region("D-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a","b","c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), FALSE)
```

get_dsaugment_region Get Ds-augment region

## Description

Given a model, calculates the candidate points region for Ds-Optimality. The user gives an initial design for which he would like to add points and specifies the weight of the new points. Then he is prompted to choose a minimum efficiency. After that, the candidate points region is calculated.

## Usage

```
get_dsaugment_region(
    init_design,
    alpha,
    model,
    parameters,
    par_values,
    par_int,
    design_space,
    calc_optimal_design,
    weight_fun = function(x) 1
)
```

## Arguments

| init_design | dataframe with "Point" and "Weight" columns that represents the initial design <br> to augment |
| :--- | :--- |
| alpha | combined weight of the new points <br> formula that represent the model with $x$ as the independent variable |
| model |  |
| parameters | character vector with the unknown parameters of the model to estimate |
| par_values | numeric vector with the initial values of the unknown parameters |
| par_int | optional numeric vector with the index of the parameters of interest for Ds- <br> optimality. |
| design_space | numeric vector with the limits of the space of the design |
| calc_optimal_design |  |
| boolean parameter, if TRUE, the optimal design is calculated and efficiencies of |  |
| the initial and augmented design are given |  |

## Value

A vector of the points limiting the candidate points region

## See Also

Other augment region: get_laugment_region()

## Examples

```
init_des <- data.frame("Point" = c(30, 60, 90), "Weight" = c(1/3, 1/3, 1/3))
get_augment_region("D-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a","b","c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), TRUE)
get_augment_region("D-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a", "b", "c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), FALSE)
```

get_laugment_region Get L-augment region

## Description

Given a model, calculates the candidate points region for L-Optimality. The user gives an initial design for which he would like to add points and specifies the weight of the new points. Then he is prompted to choose a minimum efficiency. After that, the candidate points region is calculated.

## Usage

```
get_laugment_region(
    init_design,
    alpha,
    model,
    parameters,
    par_values,
    design_space,
    calc_optimal_design,
    matB,
    weight_fun = function(x) 1
)
```

## Arguments

\(\left.$$
\begin{array}{ll}\text { init_design } & \begin{array}{l}\text { dataframe with "Point" and "Weight" columns that represents the initial design } \\
\text { to augment } \\
\text { combined weight of the new points }\end{array} \\
\text { alpha } \\
\text { model } & \begin{array}{l}\text { formula that represent the model with x as the independent variable } \\
\text { character vector with the unknown parameters of the model to estimate }\end{array} \\
\text { parameters } \\
\text { par_values } & \begin{array}{l}\text { numeric vector with the initial values of the unknown parameters }\end{array} \\
\text { design_space } & \begin{array}{l}\text { numeric vector with the limits of the space of the design }\end{array}
$$ <br>
calc_optimal_design <br>
boolean parameter, if TRUE, the optimal design is calculated and efficiencies of <br>

the initial and augmented design are given\end{array}\right]\)| optional matrix of dimensions k x k, integral of the information matrix of the |
| :--- |
| model over the interest region for I-optimality. |

## Value

A vector of the points limiting the candidate points region

## See Also

Other augment region: get_dsaugment_region()

## Examples

```
init_des <- data.frame("Point" = c(30, 60, 90), "Weight" = c(1/3, 1/3, 1/3))
get_augment_region("D-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a","b","c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), TRUE)
get_augment_region("D-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a","b","c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), FALSE)
```

```
gradient Gradient function
```

## Description

Calculates the gradient function of a model with respect to the parameters, char_vars, evaluates it at the provided values and returns the result as a function of the variable $x$.

## Usage

gradient(model, char_vars, values, weight_fun = function(x) 1)

## Arguments

model formula describing the model, which must contain only x , the parameters defined in char_vars and the numerical operators.
char_vars character vector of the parameters of the model.
values numeric vector with the nominal values of the parameters in char_vars.
weight_fun optional function variable that represents the square of the structure of variance, in case of heteroscedastic variance of the response

## Value

A function depending on $x$ that's the gradient of the model with respect to char_vars

```
gradient22 Gradient function for a subset of variables
```

## Description

Calculates the gradient function of a model with respect to a subset of the parameters given in par_int, char_vars, evaluates it at the provided values and returns the result as a function of the variable x .

## Usage

gradient22(model, char_vars, values, par_int, weight_fun = function(x) 1)

## Arguments

| model | formula describing the model, which must contain only $x$, the parameters de- <br> fined in char_vars and the numerical operators. |
| :--- | :--- |
| char_vars | character vector of the parameters of the model. |
| values | numeric vector with the nominal values of the parameters in char_vars. |
| par_int | vector of indexes indicating the subset of variables to omit in the calculation of <br> the gradient. |
| weight_fun | optional one variable function that represents the square of the structure of vari- <br> ance, in case of heteroscedastic variance of the response |

Value
A function depending on $x$ that's the gradient of the model with respect to char_vars
icrit Criterion function for I-Optimality

## Description

Calculates the value of the I-Optimality criterion function, which follows the expression:

$$
\phi_{I}=\operatorname{Tr}\left(M^{-1} \cdot B\right)
$$

## Usage

icrit(M, matB)

## Arguments

M
matB matrix of the integral of the information matrix over the interest region. Identity matrix for A-Optimality.

## Value

Numeric value of the I-optimality criterion for the information matrix.

```
inf_mat Information Matrix
```

## Description

Given the gradient vector of a model in a single variable model and a design, calculates the information matrix.

## Usage

inf_mat(grad, design)

## Arguments

grad A function in a single variable that returns the partial derivatives vector of the model.
design A dataframe that represents the design. Must have two columns:

- Point contains the support points of the design.
- Weight contains the corresponding weights of the Points.

## Value

The information matrix of the design, a $k \times k$ matrix where k is the length of the gradient.
integrate_reg_int Integrate IM

## Description

Integrates the information matrix over the region of interest to calculate matrix $B$ to be used in I-Optimality calculation.

## Usage

integrate_reg_int(grad, k, reg_int)

## Arguments

| grad | function of partial derivatives of the model. |
| :--- | :--- |
| k | number of unknown parameters of the model. |
| reg_int | optional numeric vector of two components with the bounds of the interest re- <br> gion for I-Optimality. |

## Value

The integrated information matrix.

## Description

Calculates the sensitivity function from the gradient vector, the Information Matrix and the integral of the one-point Identity Matrix over the interest region. If instead the identity matrix is used, it can be used for A-Optimality.

## Usage

isens(grad, M, matB)

## Arguments

grad A function in a single variable that returns the partial derivatives vector of the model.
M Information Matrix for the sensitivity function.
matB Matrix resulting from the integration of the one-point Information Matrix along the interest region.

## Value

The sensitivity function as a matrix of single variable.

IWFMult | Cocktail Algorithm implementation for I-Optimality and A-Optimality |
| :--- |
| (with matB $=\operatorname{diag}(k)$ ) | (with matB $=\operatorname{diag}(k)$ )

## Description

Function that calculates the I-Optimal designs given the matrix B (should be integral of the information matrix over the interest region), or A-Optimal if given $\operatorname{diag}(\mathrm{k})$. The rest of the parameters can help the convergence of the algorithm.

## Usage

IWFMult(
init_design, grad, matB, min, max, grid.length, join_thresh,

```
    delete_thresh,
    delta_weights,
    tol,
    tol2
)
```

## Arguments

init_design optional dataframe with the initial design for the algorithm. A dataframe with two columns:

- Point contains the support points of the design.
- Weight contains the corresponding weights of the Points.
grad function of partial derivatives of the model.
matB optional matrix of dimensions kx k , integral of the information matrix of the model over the interest region for I-optimality.
min numeric value with the inferior bound of the space of the design.
$\max \quad$ numeric value with the upper bound of the space of the design.
grid.length numeric value that gives the grid to evaluate the sensitivity function when looking for a maximum.
join_thresh numeric value that states how close, in real units, two points must be in order to be joined together by the join heuristic.
delete_thresh numeric value with the minimum weight, over 1 total, that a point needs to have in order to not be deleted from the design.
delta_weights numeric value in $(0,1)$, parameter of the algorithm.
tol numeric value for the convergence of the weight optimizing algorithm.
tol2 numeric value for the stop condition of the algorithm.

## Value

list correspondent to the output of the correspondent algorithm called, dependent on the criterion. A list of two objects:

- optdes: a dataframe with the optimal design in two columns, Point and Weight.
- sens: a plot with the sensitivity function to check for optimality of the design.

## See Also

Other cocktail algorithms: DWFMult(), DsWFMult(), WFMult()

## Description

L-Augments a design. The user gives an initial design for which he would like to add points and specifies the weight of the new points. Then he is prompted to choose a minimum efficiency. After that, the candidate points region is calculated and the user can choose the points and weights to add.

## Usage

laugment_design( init_design, alpha, model, parameters, par_values, design_space, calc_optimal_design, matB, weight_fun $=$ function( $x$ ) 1
)

## Arguments

\(\left.$$
\begin{array}{ll}\text { init_design } & \begin{array}{l}\text { dataframe with "Point" and "Weight" columns that represents the initial design } \\
\text { to augment }\end{array} \\
\text { alpha } & \begin{array}{l}\text { combined weight of the new points } \\
\text { formula that represents the model with } \mathrm{x} \text { as the independent variable }\end{array} \\
\text { model } \\
\text { parameters } & \begin{array}{l}\text { character vector with the unknown parameters of the model to estimate }\end{array} \\
\text { par_values } & \begin{array}{l}\text { numeric vector with the initial values of the unknown parameters }\end{array} \\
\text { design_space } & \begin{array}{l}\text { numeric vector with the limits of the space of the design }\end{array}
$$ <br>
calc_optimal_design <br>
boolean parameter, if TRUE, the optimal design is calculated and efficiencies of <br>

the initial and augmented design are given\end{array}\right]\)| optional matrix of dimensions k x k, integral of the information matrix of the |
| :--- |
| model over the interest region for I-optimality. |

## Value

A dataframe that represents the L-augmented design

## See Also

Other augment designs: daugment_design(), dsaugment_design()

## Examples

```
init_des <- data.frame("Point" = c(30, 60, 90), "Weight" = c(1/3, 1/3, 1/3))
augment_design("I-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a", "b", "c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), TRUE)
augment_design("I-Optimality", init_des, 0.25, y ~ 10^(a-b/(c+x)), c("a", "b", "c"),
    c(8.07131, 1730.63, 233.426), c(1, 100), FALSE)
```

opt_des

## Description

The opt_des function calculates the optimal design for an optimality Criterion and a model input from the user. The parameters allows for the user to customize the parameters for the cocktail algorithm in case the default set does not provide a satisfactory output. Depending on the criterion, additional details are necessary. For 'Ds-Optimality' the par_int parameter is necessary. For 'IOptimality' either the matB or reg_int must be provided.

## Usage

```
opt_des(
    Criterion,
    model,
    parameters,
    par_values = c(1),
    design_space,
    init_design = NULL,
    join_thresh = -1,
    delete_thresh = 0.02,
    delta = 1/2,
    tol = 1e-05,
    tol2 = 1e-05,
    par_int = NULL,
    matB = NULL,
    reg_int = NULL,
    desired_output = c(1, 2),
    distribution = NA,
    weight_fun = function(x) 1
)
```

## Arguments

Criterion character variable with the chosen optimality criterion. Can be one of the following:

- 'D-Optimality'
- 'Ds-Optimality'
- 'A-Optimality'
- 'I-Optimality'

| model | formula describing the model to calculate the optimal design. Must use x as the <br> variable. |
| :--- | :--- |
| parameters | character vector with the parameters of the models, as written in the formula. <br> par_values |
| numeric vector with the parameters nominal values, in the same order as given <br> in parameters. |  |
| design_space | numeric vector with the limits of the space of the design. |
| init_design | optional dataframe with the initial design for the algorithm. A dataframe with <br> two columns: | two columns:

- Point contains the support points of the design.
- Weight contains the corresponding weights of the Points.
join_thresh optional numeric value that states how close, in real units, two points must be in order to be joined together by the join heuristic.
delete_thresh optional numeric value with the minimum weight, over 1 total, that a point needs to have in order to not be deleted from the design.
delta optional numeric value in $(0,1)$, parameter of the algorithm.
tol optional numeric value for the convergence of the weight optimizing algorithm.
tol2
par_int optional numeric vector with the index of the parameters of interest for Dsoptimality.
matB optional matrix of dimensions kx k , integral of the information matrix of the model over the interest region for I-optimality.
reg_int optional numeric vector of two components with the bounds of the interest region for I-Optimality.
desired_output not functional yet: decide which kind of output you want.
distribution character variable specifying the probability distribution of the response. Can be one of the following:
- 'Homoscedasticity'
- 'Gamma', which can be used for exponential or normal heteroscedastic with constant relative error
- 'Poisson'
- 'Logistic'
- 'Log-Normal' (work in progress)
weight_fun optional one variable function that represents the square of the structure of variance, in case of heteroscedastic variance of the response

## Value

a list of two objects:

- optdes: a dataframe with the optimal design in two columns, Point and Weight.
- sens: a plot with the sensitivity function to check for optimality of the design.

## Examples

```
opt_des("D-Optimality", y ~ a * exp(-b / x), c("a", "b"), c(1, 1500), c(212, 422))
```

```
plot.optdes Plot function for optdes
```

## Description

Plot function for optdes

## Usage

\#\# S3 method for class 'optdes'
plot(x, ...)

## Arguments

x
An object of class optdes.
... Possible extra arguments for plotting dataframes

## Examples

```
rri <- opt_des(Criterion = "I-Optimality", model = y ~ a * exp(-b / x),
    parameters = c("a", "b"), par_values = c(1, 1500), design_space = c(212, 422),
    reg_int = c(380, 422))
plot(rri)
```

plot_convergence Plot Convergence of the algorithm

## Description

Plots the criterion value on each of the steps of the algorithm, both for optimizing weights and points, against the total step number.

## Usage

plot_convergence(convergence)

## Arguments

convergence A dataframe with two columns:

- criteria contains value of the criterion on each step.
- step contains number of the step.

## Value

A ggplot object with the criteria in the y axis and step in the x axis.

```
plot_sens Plot sensitivity function
```

## Description

Plots the sensitivity function and the value of the Equivalence Theorem as an horizontal line, which helps assess the optimality of the design of the given sensitivity function.

## Usage

plot_sens(min, max, sens_function, criterion_value)

## Arguments

min $\quad$ Minimum of the space of the design, used in the limits of the representation.
$\max \quad$ Maximum of the space of the design, used in the limits of the representation.
sens_function A single variable function, the sensitivity function.
criterion_value
A numeric value representing the other side of the inequality of the Equivalence Theorem.

Value
A ggplot object that represents the sensitivity function
print.optdes

```
print.optdes

\section*{Description}

Print function for optdes

\section*{Usage}
```

## S3 method for class 'optdes'

print(x, ...)

```

\section*{Arguments}
x
An object of class optdes.
... Possible extra arguments for printing dataframes

\section*{Examples}
```

rri <- opt_des(Criterion = "I-Optimality", model = y ~ a * exp(-b / x),
parameters = c("a", "b"), par_values = c(1, 1500), design_space = c(212, 422),
reg_int = c(380, 422))
print(rri)

```
    sens
    Master function to calculate the sensitivity function

\section*{Description}

Calculates the sensitivity function given the desired Criterion, an information matrix and other necessary values depending on the chosen criterion.

\section*{Usage}
sens(Criterion, grad, M, par_int = c(1), matB = NA)

\section*{Arguments}

Criterion character variable with the chosen optimality criterion. Can be one of the following:
- 'D-Optimality'
- 'Ds-Optimality'
- 'A-Optimality'
- 'I-Optimality'
grad A function in a single variable that returns the partial derivatives vector of the model.

M Information Matrix for the sensitivity function.
par_int Numeric vector of the indexes of the parameters of interest for Ds-Optimality.
matB Matrix resulting from the integration of the one-point Information Matrix along the interest region.

\section*{Value}

The sensitivity function as a matrix of single variable.
```

shiny_augment Shiny D-augment

```

\section*{Description}

Launches the demo shiny application to D -augment several prespecified models

\section*{Usage}
shiny_augment()

\section*{Examples}
shiny_augment()
```

shiny_optimal Shiny Optimal

```

\section*{Description}

Launches the demo shiny application to calculate optimal designs for Antoine's Equation

\section*{Usage}
shiny_optimal()

\section*{Examples}
shiny_optimal()
\(\qquad\)
summary.optdes Summary function for optdes

\section*{Description}

Summary function for optdes

\section*{Usage}
\#\# S3 method for class 'optdes'
summary(object, ...)

\section*{Arguments}
object An object of class optdes.
... Possible extra arguments for the summary

\section*{Examples}
```

rri <- opt_des(Criterion = "I-Optimality", model = y ~ a * exp(-b / x),
parameters = c("a", "b"), par_values = c(1, 1500), design_space = c(212, 422),
reg_int = c(380, 422))
summary(rri)

```
    tr
        Trace

\section*{Description}

Return the mathematical trace of a matrix, the sum of its diagonal elements.

\section*{Usage}
\(\operatorname{tr}(\mathrm{M})\)

\section*{Arguments}

M
The matrix from which to calculate the trace.

\section*{Value}

The trace of the matrix.
```

update_design Update Design with new point

```

\section*{Description}

Updates a design adding a new point to it. If the added point is closer than delta to an existing point of the design, the two points are merged together as their arithmetic average. Then updates the weights to be equal to all points of the design.

\section*{Usage}
update_design(design, xmax, delta, new_weight)

\section*{Arguments}
\begin{tabular}{ll} 
design & \begin{tabular}{l} 
Design to update. It's a dataframe with two columns: \\
• Point contains the support points of the design.
\end{tabular} \\
• Weight contains the corresponding weights of the Points.
\end{tabular}

\section*{Value}

The updated design.
```

update_design_total Merge close points of a design

```

\section*{Description}

Takes a design and merge together all points that are closer between them than a certain threshold delta.

\section*{Usage}
update_design_total(design, delta)

\section*{Arguments}
design The design to update. It's a dataframe with two columns:
- Point contains the support points of the design.
- Weight contains the corresponding weights of the Points.
delta Threshold which defines how close two points have to be to any of the existing ones in order to merge with them.

\section*{Value}

The updated design.
update_sequence Deletes duplicates points

\section*{Description}

Within a vector of points, deletes points that are close enough (less than the tol parameter). Returns the points without the "duplicates"

\section*{Usage}
update_sequence(points, tol)

\section*{Arguments}
points Points to be updated
tol Tolerance for which two points are considered the same

\section*{Value}

The points without duplicates
```

update_weights Update weight D-Optimality

```

\section*{Description}

Implementation of the weight update formula for D-Optimality used to optimize the weights of a design, which is to be applied iteratively until no sizable changes happen.

\section*{Usage}
update_weights(design, sens, k, delta)

\section*{Arguments}
design Design to optimize the weights from. It's a dataframe with two columns:
- Point contains the support points of the design.
- Weight contains the corresponding weights of the Points.
sens Sensibility function for the design and model.
\(k \quad\) Number of parameters of the model.
delta A parameter of the algorithm that can be tuned. Must be \(0<\) delta \(<1\).

\section*{Value}
returns the new weights of the design after one iteration.
```

update_weightsDS Update weight Ds-Optimality

```

\section*{Description}

Implementation of the weight update formula for Ds-Optimality used to optimize the weights of a design, which is to be applied iteratively until no sizable changes happen.

\section*{Usage}
update_weightsDS(design, sens, s, delta)

\section*{Arguments}
\[
\begin{array}{ll}
\text { design } & \text { Design to optimize the weights from. It's a dataframe with two columns: } \\
\text { - Point contains the support points of the design. } \\
\text { - Weight contains the corresponding weights of the Points. } \\
\text { sens } & \begin{array}{l}
\text { Sensibility function for the design and model. } \\
\text { s }
\end{array} \\
\text { number of parameters of interest of the model } \\
\text { delta } & \text { A parameter of the algorithm that can be tuned. Must be } 0<\text { delta } a<1 .
\end{array}
\]

\section*{Value}
returns the new weights of the design after one iteration.
```

update_weightsI Update weight I-Optimality

```

\section*{Description}

Implementation of the weight update formula for I-Optimality used to optimize the weights of a design, which is to be applied iteratively until no sizable changes happen. A-Optimality if instead of the integral matrix the identity function is used.

\section*{Usage}
update_weightsI(design, sens, crit, delta)

\section*{Arguments}
design Design to optimize the weights from. It's a dataframe with two columns:
- Point contains the support points of the design.
- Weight contains the corresponding weights of the Points.
sens Sensibility function for the design and model.
crit Value of the criterion function for I-Optimality.
delta A parameter of the algorithm that can be tuned. Must be \(0<\) delta \(<1\).

\section*{Value}
returns the new weights of the design after one iteration.
```

weight_function Weight function per distribution

```

\section*{Description}

Weight function per distribution

\section*{Usage}
weight_function(model, char_vars, values, distribution = "Homoscedasticity")

\section*{Arguments}
\begin{tabular}{ll} 
model & formula describing the model to use. Must use x as the variable. \\
char_vars & character vector with the parameters of the models, as written in the formula \\
values & numeric vector with the parameters nominal values, in the same order as given \\
in parameters. \\
distribution \\
character variable specifying the probability distribution of the response. Can \\
be one of the following: \\
- 'Homoscedasticity' \\
- 'Gamma', which can be used for exponential or normal heteroscedastic \\
- 'Pith constant relative error
\end{tabular}

\section*{Value}
one variable function that represents the square of the structure of variance, in case of heteroscedastic variance of the response.
```

WFMult

```

Master function for the cocktail algorithm, that calls the appropriate one given the criterion.

\section*{Description}

Depending on the Criterion the cocktail algorithm for the chosen criterion is called, and the necessary parameters for the functions are given from the user input.

\section*{Usage}
```

WFMult(
init_design,
grad,
Criterion,
par_int = NA,
matB = NA,
min,
max,
grid.length,
join_thresh,
delete_thresh,
k,
delta_weights,
tol,
tol2
)

```

\section*{Arguments}
init_design optional dataframe with the initial design for the algorithm. A dataframe with two columns:
- Point contains the support points of the design.
- Weight contains the corresponding weights of the Points.
grad function of partial derivatives of the model.
Criterion character variable with the chosen optimality criterion. Can be one of the following:
- 'D-Optimality'
- 'Ds-Optimality'
- 'A-Optimality'
- 'I-Optimality'
par_int numeric vector with the index of the parameters of interest. Only necessary when the Criterion chosen is 'Ds-Optimality'.
matB optional matrix of dimensions kx k , integral of the information matrix of the model over the interest region for I-optimality.
\begin{tabular}{ll} 
min & numeric value with the inferior bound of the space of the design. \\
max & numeric value with the upper bound of the space of the design. \\
grid. length & \begin{tabular}{l} 
numeric value that gives the grid to evaluate the sensitivity function when look- \\
ing for a maximum.
\end{tabular} \\
join_thresh & \begin{tabular}{l} 
numeric value that states how close, in real units, two points must be in order to \\
be joined together by the join heuristic.
\end{tabular} \\
delete_thresh & \begin{tabular}{l} 
numeric value with the minimum weight, over 1 total, that a point needs to have \\
in order to not be deleted from the design.
\end{tabular} \\
k & \begin{tabular}{l} 
number of unknown parameters of the model.
\end{tabular} \\
delta_weights & \begin{tabular}{l} 
numeric value in \((0,1)\), parameter of the algorithm.
\end{tabular} \\
tol & numeric value for the convergence of the weight optimizing algorithm. \\
tol2 & numeric value for the stop condition of the algorithm.
\end{tabular}

\section*{Value}
list correspondent to the output of the correspondent algorithm called, dependent on the criterion. A list of two objects:
- optdes: a dataframe with the optimal design in two columns, Point and Weight.
- sens: a plot with the sensitivity function to check for optimality of the design.
