## Using Python to parse and present Windows 64 bit timestamps

January 16, 2010 [Integriography](#) [Leave a comment](#) [Go to comments](#)

I'm working on learning Python since Perl, even after 20 years, still doesn't stick in my head. The phrase "like a duck to water" doesn't quite apply to my experience with Python, but I'm certainly swimming along nicely.

Since I learn languages and tools more effectively when I have a real problem to work on, I set out to parse the NTFS MFT record using Python. This was going swimmingly until I hit the file MAC times. According to Microsoft:

"A file time is a 64-bit value that represents the number of 100-nanosecond intervals that have elapsed since 12:00 A.M. January 1, 1601 Coordinated Universal Time (UTC)."

So, two problems: 1) It is a 64 bit value and python only has 32 bit longs and b) it doesn't use the Unix definition of epoch.

After a lot of false starts, I learned the power of dictionaries and classes and came up with the following:

```
from datetime import date, datetime

class WindowsTime:
    def __init__(self, low, high):
        self.low = long(low)
        self.high = long(high)

        self.unixtime = self.GetUnixTime()
        self.utc = datetime.utcfromtimestamp(self.unixtime)
        self.utcstr = self.utc.strftime("%Y/%m/%d %H:%M:%S.%f")

# Windows NT time is specified as the number of 100 nanosecond intervals since January 1, 1601.
# UNIX time is specified as the number of seconds since January 1, 1970.
# There are 134,774 days (or 11,644,473,600 seconds) between these dates.
    def GetUnixTime(self):
        t=float(self.high)*2**32 + self.low
        return (t*1e-7 - 11644473600)
```

I have a module that defines a dictionary and parses chunks of data read from the MFT:

```
# Decodes the Standard Information attribute in a MFT r
def decodeSirecord(s):

    d = {}
    d['crttime'] = WindowsTime(struct.un
```

Follow

Follow

"Integriography: A

```
struct.unj
```

...

Then just do:

```
SIObjct = decodeSirecord(data)
```

And you can print the times out directly from the

```
print "CRTIME: %s" % (SIObjct['crti
```

This isn't rocket science, and there's probably  
filesystems and metadata, this could come in han

[Reply](#)

Try using the unsigned long long 'Q' for 64-bit values.

```
i.e. ft = struct.unpack('<Q',fh.read(8))[0]
```

Cheers,  
Syd
